Activity 3 – Case Analysis: Accessibility of Philippine E-Government Websites

Case Analysis Table

Accessibility / Inclusivity Issue Identified	Evidence or Finding from the Article	User/s Who May Be Affected	How Does It Affect User Interaction?	Proposed Improvement
1. Missing or Bad Image Descriptions (ALT Text)	Table 8 shows that only 51.85% of websites used proper ALT tags for images. Also, only 48.15% provided good ALT text for all pictures, image buttons, and photo links.	People who are blind, people with low vision, and screen reader users.	Screen reader software cannot explain what an image shows or does. Users only hear generic file names or blank spaces, so they miss key information or link details.	Add short, clear descriptions (alt text) to all informative pictures and buttons. Use empty tags (alt="") or CSS code for pictures used only for decoration.
2. Unlabeled Form Boxes and Hard CAPTCHA Security Checks	Table 8 shows that text labels connected to form input boxes reached only 62.96% compliance. Table 7 shows CAPTCHA compliance was only 18.52%.	Blind users, screen reader users, people with hand or movement difficulties, and people with thinking or learning differences.	Unlabeled boxes mean screen readers cannot tell users what to type (like name vs. email). Picture CAPTCHAs block blind users and confuse users who have trouble reading blurred text.	Connect <label> tags directly to input box IDs in the code, and replace image CAPTCHAs with sound-based CAPTCHAs or automatic checks like reCAPTCHA v3.
3. Videos and Audio Without Captions or Text Transcripts	Table 8 shows that embedded media had accessible text labels on only 51.85% of the websites.	Deaf users, hard-of-hearing users, and people in noisy places or with slow internet connection.	Deaf users cannot understand spoken information or news in government videos and audio clips.	Require all government agencies to add subtitles (closed captions) and written text transcripts to their videos and audio files.

4. Missing Location Cues, Unclear Menus, and Missing Site Maps	Table 8 shows that showing the user's current page location scored only 59.26%. Well-organized site maps were present on only 48.15% of sites.	People with cognitive difficulties, elderly citizens, screen reader users, and people with physical motor difficulties.	Users easily get lost inside deep government websites. This makes them tired and frustrated when trying to find public services.	Put simple location links (breadcrumbs) on every page, make standard navigation menus, and keep an organized site map that screen readers can read easily.
5. Missing Agency Info and Contact Details	Table 8 shows low scores for contact details: Mobile Numbers (37.04%), Fax Numbers (29.63%), Key Official Corner (48.15%), and Feedback Forms (59.26%).	People who need help, citizens with disabilities needing assistance, and non-tech-savvy users.	Citizens cannot directly contact agency workers to ask questions, report website problems, or get help with services.	Follow the Government Website Template Design (GWTD) rules to display all office details, active phone numbers, and working feedback forms on every site.
6. Low Online Features, Poor Mobile Support, and Lack of Interactive Tools	Table 5 and 7 show that the Connected stage averaged only 18.52% compliance, with 0% for e-signatures and opinion polls, and 7.41% for mobile messaging. Section 5.2 notes a lack of responsive mobile design.	Citizens with physical or movement disabilities, citizens in far rural areas using mobile phones, and people who need online service forms.	Citizens must travel in person to government offices because websites do not work well on mobile phones and lack online form submissions, digital signatures, or feedback features.	Make all websites automatically fit mobile phone screens (responsive design), add safe digital signature features, create online application forms, and add citizen feedback tools.

Final Analysis

The study of 27 Philippine government websites by Bokingkito et al. (2025) shows that websites are okay at basic accessibility, but weak at providing online services. Government websites got a decent average score of 82.50% for Web Accessibility under WCAG 2.0 rules, but scored only 53.43% for Web Presence under GWTD guidelines, dropping to 18.52% in the Connected stage. Main problems like missing image descriptions (48.15%–51.85%), missing form box labels (62.96%), uncaptioned videos (51.85%), and missing location cues (59.26%) make it hard for citizens with visual, hearing, cognitive, and movement disabilities to use these websites. Also, because websites do not work well on phones and lack digital signatures, citizens with movement limitations are forced to visit real offices in person. To fix this, Philippine government agencies must test their sites regularly, add proper code tags, support mobile screens, and build complete online service systems.
